

# **Introduction to Software Testing (2nd edition) Chapter 3**

## **Test Automation**

Paul Ammann & Jeff Offutt

<http://www.cs.gmu.edu/~offutt/softwaretest/>

*Updated October 2018*

# What is Test Automation?

The use of software to control the execution of tests, the comparison of actual outcomes to predicted outcomes, the setting up of test preconditions, and other test control and test reporting functions

- Reduces **cost**
- Reduces **human error**
- Reduces **variance** in test quality from different individuals
- Significantly reduces the cost of **regression** testing

# Software Testability (3.1)

The degree to which a system or component facilitates the establishment of test criteria and the performance of tests to determine whether those criteria have been met

- Plainly speaking – how hard it is to find faults in the software
- Testability is dominated by two practical problems
  - How to provide the test values to the software
  - How to observe the results of test execution

# Observability and Controllability

## ■ Observability

How easy it is to observe the behavior of a program in terms of its outputs, effects on the environment and other hardware and software components

- Software that affects hardware devices, databases, or remote files have low observability

## ■ Controllability

How easy it is to provide a program with the needed inputs, in terms of values, operations, and behaviors

- Easy to control software with inputs from keyboards
- Inputs from hardware sensors or distributed software is harder

■ **Data abstraction** reduces controllability and observability

# Components of a Test Case (3.2)

- A test case is a **multipart artifact** with a definite structure

- Test case values

The input values needed to complete an execution of the software under test

- Expected results

The result that will be produced by the test if the software behaves as expected

- A **test oracle** uses expected results to decide whether a test passed or failed

# Affecting Controllability and Observability

## ■ Prefix values

Inputs necessary to put the software into the appropriate state to receive the test case values

## ■ Postfix values

Any inputs that need to be sent to the software after the test case values are sent

1. *Verification Values* : Values needed to see the results of the test case values
2. *Exit Values* : Values or commands needed to terminate the program or otherwise return it to a stable state

# Putting Tests Together

## ■ Test case

The test case values, prefix values, postfix values, and expected results necessary for a complete execution and evaluation of the software under test

## ■ Test set

A set of test cases

## ■ Executable test script

A test case that is prepared in a form to be executed automatically on the test software and produce a report

# Test Automation Framework (3.3)

A set of assumptions, concepts, and tools  
that support test automation

# What is JUnit?

- Open source Java testing framework used to write and run repeatable **automated tests**
- JUnit is open source (**junit.org**)
- A structure for writing **test drivers**
- JUnit **features** include:
  - **Assertions** for testing expected results
  - Test features for sharing **common test data**
  - Test **suites** for easily organizing and running tests
  - Graphical and textual **test runners**
- JUnit is **widely used** in industry
- JUnit can be used as **stand alone** Java programs (from the command line) or **within an IDE** such as Eclipse

# JUnit Tests

- JUnit can be used **to test** ...
  - ... an entire object
  - ... part of an object – a method or some interacting methods
  - ... interaction between several objects
- It is primarily intended for unit and integration testing, not system testing
- Each test is embedded into one **test method**
- A **test class** contains one or more test methods
- Test classes **include** :
  - A collection of **test methods**
  - Methods to **set up** the state before and **update** the state after each test and before and after all tests
- Get started at **junit.org**

# Writing Tests for JUnit

- Need to use the methods of the `junit.framework.assert` class
  - javadoc gives a complete description of its capabilities
- Each test method checks a condition (**assertion**) and reports to the test runner whether the test failed or succeeded
- The test runner uses the result to **report to the user** (in command line mode) or update the display (in an IDE)
- All of the methods **return void**
- A few representative methods of `junit.framework.assert`
  - `assertTrue (boolean)`
  - `assertTrue (String, boolean)`
  - `fail (String)`

# JUnit Test Fixtures

- A **test fixture** is the state of the test
  - Objects and variables that are used by more than one test
  - Initializations (*prefix* values)
  - Reset values (*postfix* values)
- Different tests can **use** the objects without sharing the state
- Objects used in test fixtures should be declared as **instance variables**
- They should be initialized in a **@Before** method
- Can be deallocated or reset in an **@After** method

# Simple JUnit Example

*Note: JUnit 4 syntax*

```
public class Calc
{
    static public int add (int a, int b)
    {
        return a + b;
    }
}
```

Printed if  
assert fails

Expected  
output

```
import org.junit.Test;
import static org.junit.Assert.*;

public class CalcTest
{
    @Test public void testAdd()
    {
        assertTrue ("Calc sum incorrect",
                    5 == Calc.add (2, 3));
    }
}
```

Test  
values

# Testing the Min Class

```
import java.util.*;

public class Min {
    public static <T extends Comparable<? super T>> T min (List<? extends T> list)
    {
        if (list.size() == 0)
        {
            throw new IllegalArgumentException ("Min.min");
        }
        Iterator<? extends T> itr = list.iterator();
        T result = itr.next();

        if (result == null) throw new NullPointerException ("Min.min");

        while (itr.hasNext())
        { // throws NPE, CCE as needed
            T comp = itr.next();
            if (comp.compareTo (result) < 0)
            {
                result = comp;
            }
        }
        return result;
    }
}
```

# MinTest Class

- Standard imports for all JUnit classes :

```
import static org.junit.Assert.*;  
import org.junit.*;  
import java.util.*;
```

- Test fixture and pre-test setup method (prefix) :

```
private List<String> list; // Test fixture  
  
// Set up - Called before every test method.  
@Before  
public void setUp()  
{  
    list = new ArrayList<String>();  
}
```

- Post test teardown method (postfix) :

```
// Tear down - Called after every test method.  
@After  
public void tearDown()  
{  
    list = null; // redundant in this example  
}
```

# Min Test Cases: NullPointerException

```
@Test public void testForNullList()
{
    list = null;
    try {
        Min.min (list);
    } catch (NullPointerException e) {
        return;
    }
    fail ("NullPointerException expected")
}
```

This **NullPointerException** test uses the **fail** assertion

This **NullPointerException** test catches an easily overlooked special case

This **NullPointerException** test decorates the **@Test** annotation with the class of the exception

```
@Test (expected = NullPointerException.class)
public void testForNullElement()
{
    list.add (null);
    list.add ("cat");
    Min.min (list);
}
```

```
@Test (expected = NullPointerException.class)
public void testForSoloNullElement()
{
    list.add (null);
    Min.min (list);
}
```

# More Exception Test Cases for Min

```
@Test (expected = ClassCastException.class)
@SuppressWarnings ("unchecked")
public void testMutuallyIncomparable()
{
    List list = new ArrayList();
    list.add ("cat");
    list.add ("dog");
    list.add (1);
    Min.min (list);
}
```

**Note that Java  
generics don't  
prevent clients from  
using raw types!**

```
@Test (expected = IllegalArgumentException.class)
public void testEmptyList()
{
    Min.min (list);
}
```

**Special case: Testing for the  
empty list**

# Remaining Test Cases for Min

```
@Test
public void testSingleElement()
{
    list.add ("cat");
    Object obj = Min.min (list);
    assertTrue ("Single Element List", obj.equals ("cat"));
}
```

```
@Test
public void testDoubleElement()
{
    list.add ("dog");
    list.add ("cat");
    Object obj = Min.min (list);
    assertTrue ("Double Element List", obj.equals ("cat"));
}
```

**Finally! A couple of  
“Happy Path” tests**

# Summary: Seven Tests for Min

## ■ Five tests with exceptions

1. null list
2. null element with multiple elements
3. null single element
4. incomparable types
5. empty elements

## ■ Two without exceptions

6. single element
7. two elements

# Data-Driven Tests

- **Problem** : Testing a function multiple times with similar values
  - How to avoid test code bloat?
- **Simple example** : Adding two numbers
  - Adding a given pair of numbers is just like adding any other pair
  - You really only want to write one test
- **Data-driven** unit tests call a constructor for each collection of test values
  - Same tests are then run on each set of data values
  - Collection of data values defined by method tagged with `@Parameters` annotation

# Example JUnit Data-Driven Unit Test

```
import org.junit.*;
import org.junit.runner.RunWith;
import org.junit.runners.Parameterized;
import org.junit.runners.Parameterized.Parameters;
import static org.junit.Assert.*;
import java.util.*;
```

```
@RunWith (Parameterized.class)
public class DataDrivenCalcTest
{ public int a, b, sum;
```

Constructor is  
called for each  
triple of values

```
public DataDrivenCalcTest (int v1, int v2, int expected)
{ this.a = v1; this.b = v2; this.sum = expected; }
```

```
@Parameters public static Collection<Object[]> parameters()
{ return Arrays.asList (new Object [][] {{1, 1, 2}, {2, 3, 5}}); }
```

```
@Test public void additionTest()
{ assertTrue ("Addition Test", sum == Calc.add (a, b)); }
}
```

Test 1  
Test values: 1, 1  
Expected: 2

Test 2  
Test values: 2, 3  
Expected: 5

Test method

# Tests with Parameters: JUnit Theories

- Unit tests can have actual parameters
  - So far, we've only seen parameterless test methods
- Contract model: Assume, Act, Assert
  - *Assumptions* (preconditions) limit values appropriately
  - *Action* performs activity under scrutiny
  - *Assertions* (postconditions) check result

```
@Theory public void removeThenAddDoesNotChangeSet (  
    Set<String> someSet, String str) {                // Parameters!  
    assertTrue (someSet != null)                      // Assume  
    assertTrue (someSet.contains (str)) ;              // Assume  
    Set<String> copy = new HashSet<String>(someSet);   // Act  
    copy.remove (str);  
    copy.add (str);  
    assertTrue (someSet.equals (copy));                // Assert  
}
```

# Question: Where Do The Data Values Come From?

■ Answer:

- All combinations of values from @DataPoints annotations where assume clause is true
- Four (of nine) combinations in this particular case
- Note: @DataPoints format is an array

@DataPoints

```
public static String[] animals = {"ant", "bat", "cat"};
```

@DataPoints

```
public static Set[] animalSets = {  
    new HashSet (Arrays.asList ("ant", "bat")),  
    new HashSet (Arrays.asList ("bat", "cat", "dog", "elk")),  
    new HashSet (Arrays.asList ("Snap", "Crackle", "Pop"))  
};
```

Nine combinations of  
animalSets[i].contains (animals[j])  
is false for five combinations

# JUnit Theories Need BoilerPlate

```
import org.junit.*;
import org.junit.runner.RunWith;
import static org.junit.Assert.*;
import static org.junit.Assume.*;

import org.junit.experimental.theories.DataPoint;
import org.junit.experimental.theories.DataPoints;
import org.junit.experimental.theories.Theories;
import org.junit.experimental.theories.Theory;

import java.util.*;

@RunWith (Theories.class)
public class SetTheoryTest
{
    ... // See Earlier Slides
}
```

# Running from a Command Line

- This is all we need to run JUnit in an IDE (like Eclipse)
- We need a `main()` for command line execution ...

# AllTests

```
import org.junit.runner.RunWith;
import org.junit.runners.Suite;
import junit.framework.JUnit4TestAdapter;

// This section declares all of the test classes in the program.
@RunWith (Suite.class)
@Suite.SuiteClasses ({ StackTest.class }) // Add test classes here.

public class AllTests
{
    // Execution begins in main(). This test class executes a
    // test runner that tells the tester if any fail.
    public static void main (String[] args)
    {
        junit.textui.TestRunner.run (suite());
    }

    // The suite() method helps when using JUnit 3 Test Runners or Ant.
    public static junit.framework.Test suite()
    {
        return new JUnit4TestAdapter (AllTests.class);
    }
}
```

# JUnit 5 changes: min() Example

- JUnit 5 uses assertions, not annotations, for exceptions

```
@Test public void testForNullList()
{
    assertThrows(NullPointerException.class, () -> Min.min(null));
}
```

## ■ Other JUnit 5 differences

- Java lambda expressions play a role
- @Before, @After change to @BeforeEach, @AfterEach
- imports, some assertions change
- Test runners change (no simple replacement for AllTests.java)
- @Theory construct moved to 3<sup>rd</sup> party extensions
  - google “property based testing”

## ■ See MinTestJUnit5.java on the book website

# How to Run Tests

- JUnit provides **test drivers**
  - **Character-based** test driver runs from the command line
  - GUI-based test driver-*junit.swingui.TestRunner*
    - Allows programmer to specify the test class to run
    - Creates a “**Run**” button
- If a test fails, JUnit gives the **location** of the failure and any **exceptions** that were thrown

# Summary

- The only way to make testing **efficient** as well as **effective** is to **automate** as much as possible
- Test frameworks provide very simple ways to **automate** our tests
- It is no “**silver bullet**” however ... it does not solve the hard problem of testing :

**What test values to use ?**

- This is test design ... the purpose of **test criteria**
